

Turn on intercepting options in burp suite

1. Install foxy proxy and use chromium or any other browser
2. Use burp suite to capture request from one of the links
3. Paste that request and make a new file with the nano terminal editors
4. Take the variable tbname (this is the var in our case) from the request and put in the variable **-p flag**
5. Change the **-r flag variable with the file name we just created**
6. We will now use **SqlMap** to scan the site
7. It will iteratively go through the possible passwords and retrieve working ones and will dump it in a new file
